

Object Constraint Language (OCL) Timing Diagrams

Model Driven Architecture (MDA)

OCL

Characters of OCL

Timing diagrams

Examples

Model Driven Architecture (MDA)

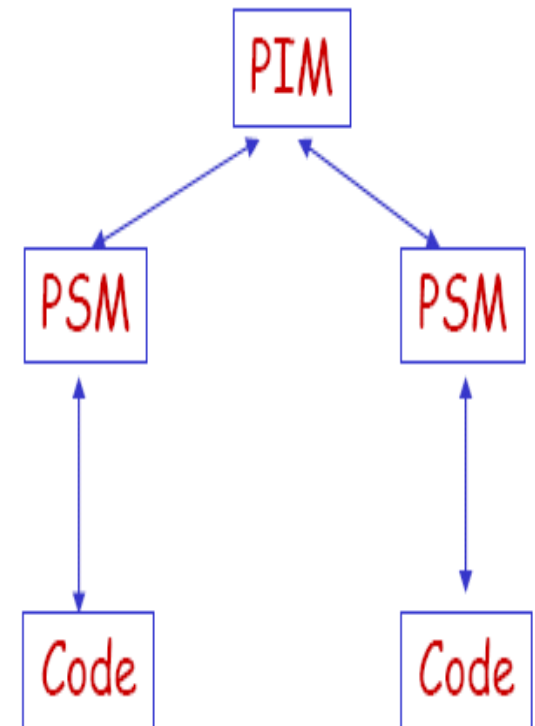

- In Model Driven Architecture (MDA), the software development process is driven by the activity of modeling.
- The MDA framework defines how to specify and transform models at different abstraction levels.
- MDA is under supervision of the Object Management Group (OMG).
- More info: *MDA Explained: The Model Driven Architecture: Practice and Promise, Addison-Wesley, 2003.*

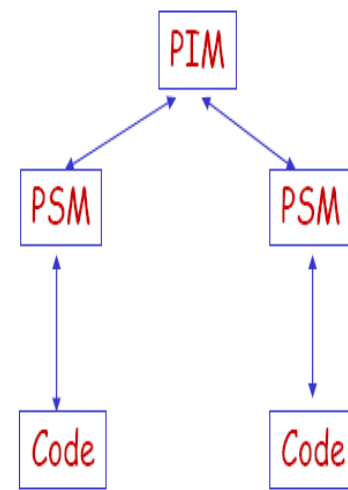

The MDA Process

The MDA process consists of three steps:

- Build a model with a high level of abstraction, called ***Platform Independent Model (PIM)***.
- Transform the PIM into one or more ***Platform Specific Models (PSMs)***, i.e., models that are specified in some specific implementation technology.
- Transform the PSMs to code.

MDA Elements

- Models are the basis of MDA.
- Models must be consistent and precise, and contain as much information as possible.
- Modeling languages describe models.
- These languages must be well-defined to enable automatic transformation.
- Transformation tools do the dirty work.
- PIM-to-PSM is more challenging than PSM-to-Code.
- Transformation definitions map one model to another.
- These definitions must be independent on the tools.

MDA Benefits

- Portability - PIMs can be transformed to different PSMs.
- Productivity - developers work at a higher level abstraction.
- Cross-platform interoperability - PIMs serve as a bridge between different PSMs.
- Easier maintenance and documentation
- Maintaining PIMs is much easier than maintaining code.

Maturity Levels

The maturity level indicates the gap between the model and the system.

- Level 0: No specification - Everything is in mind.
- Level 1: Textual description - Informal English description.
- Level 2: Text with Diagrams - Use diagrams to help understanding.
- Level 3: Models with Text - Models have well-defined meaning
- Level 4: Precise models - Precise enough to enable automatic model-to-code transformation.
- Level 5: Models only - Code is invisible.

UML, OCL, and MDA

- UML uses diagrams to express software design.
- Diagrams are easier to understand, but many properties cannot be expressed using diagrams alone.
- The use of OCL (Object Constraint Language) can add additional and necessary info to UML diagrams.
- OCL uses expressions that have solid mathematic foundation but still maintains the ease of use.
- Combining UML and OCL is necessary to construct models at maturity level 4 - models precise enough to enable automatic model-to-code transformation.
- The application of MDA relies on Level 4 models.

OCL Language Description

(SOURCE: Object Constraint Language, OMG Spec. Ver.2.0, May 2006)

- OCL - a formal language that remains easy to read and write
- OCL is a pure specification language - no side effects (an OCL expression simply returns a value and change anything in the model)
- OCL is not a programming but modeling language - it is not possible to write program logic or flow control in OCL
- The evaluation of an OCL expression is instantaneous. This means that the states of objects in a model cannot change during evaluation

OCL Context

- The *context* keyword introduces the context for the expression – class, attribute, operation, operation parameter, ...
- The keyword **inv**, **pre**, and **post** denote the stereotypes, respectively «invariant», «precondition», and «postcondition» of the constraint.
- The actual OCL expression comes after the colon.

context TypeName inv:

'this is an OCL expression with stereotype <<invariant>> in the context of TypeName' = 'another string'

Invariants 1/2

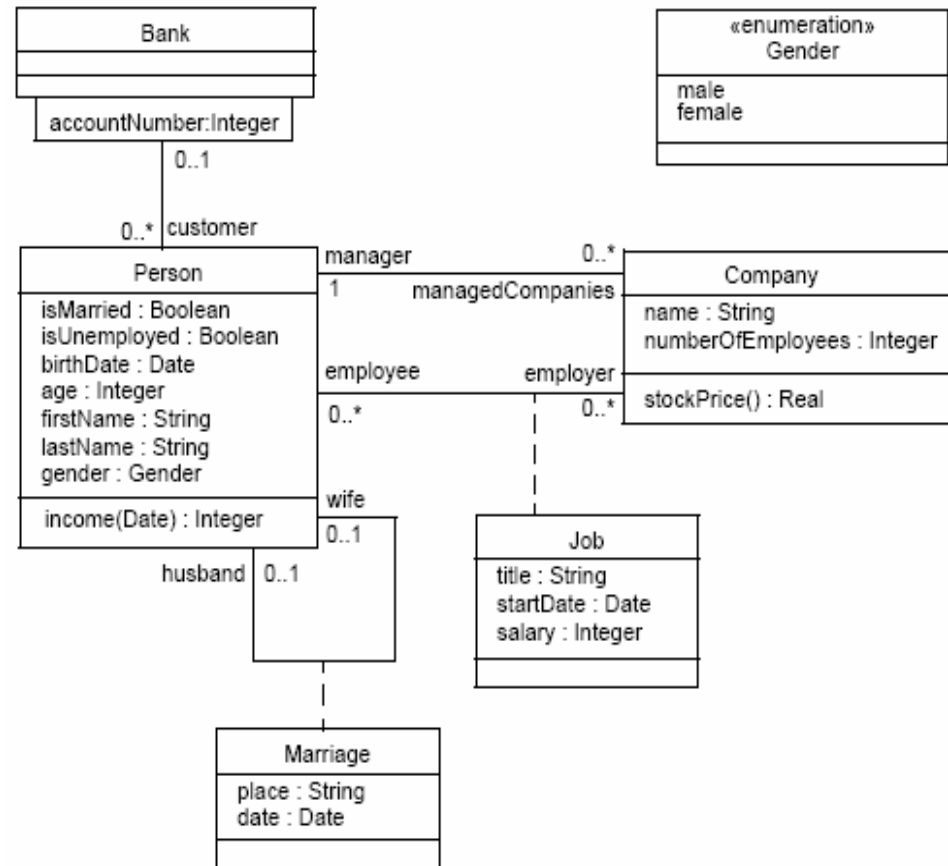

- The OCL expression can be part of an Invariant which is a Constraint stereotyped as an «invariant».
- An OCL expression is an invariant of the type and must be true for all instances of that type at any time.
- All OCL expressions that express invariants are of type Boolean.

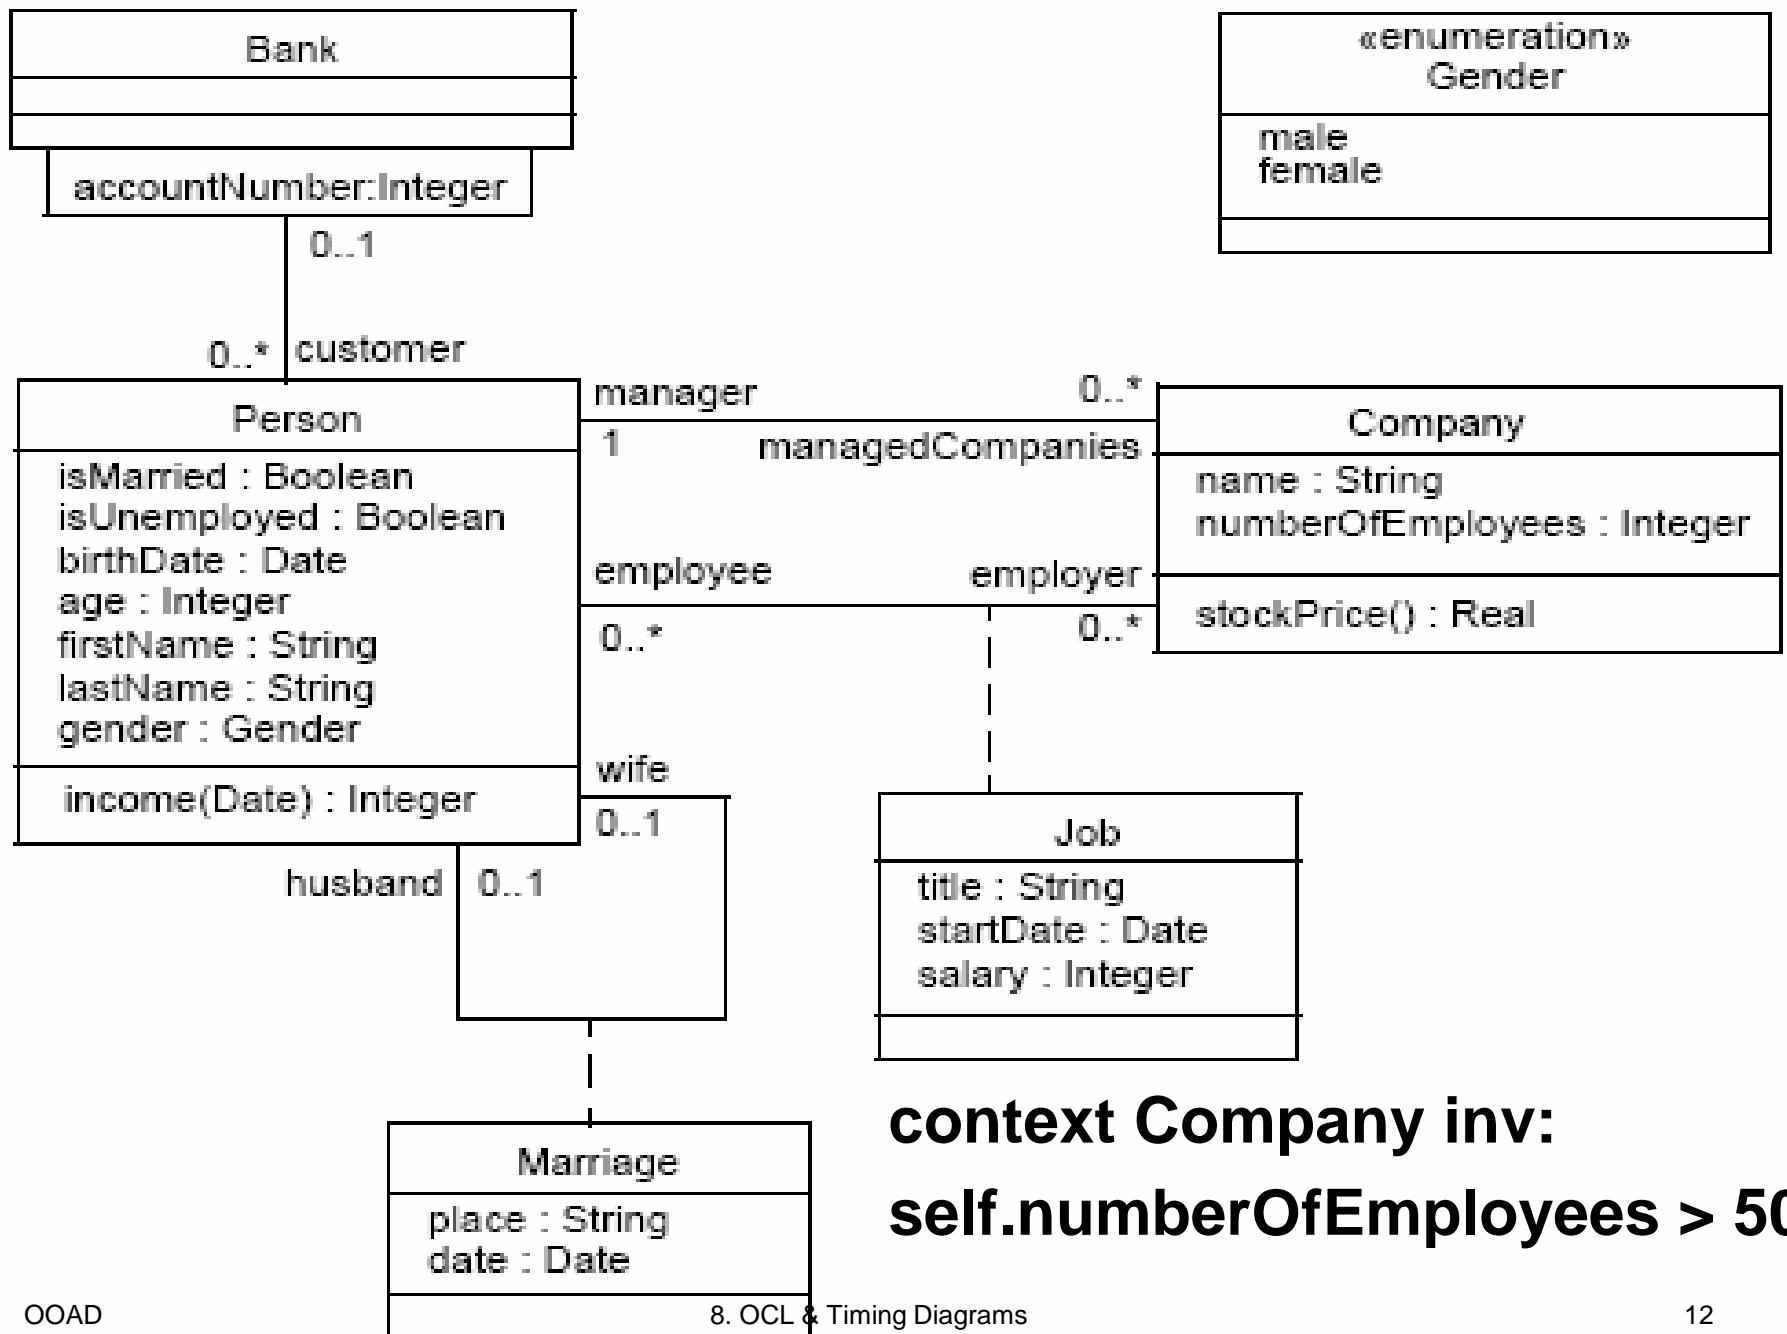

Invariants 2/2

- in the context of the Company type, the following expression would specify an invariant that the number of employees must always exceed 50:

context Company inv:
self.numberOfEmployees > 50
-- self is an instance of type Company (refers to the contextual instance)

context Company inv:
self.numberOfEmployees > 50

Omitting *self*

context Company inv:
self.numberOfEmployees > 50

context c : Company inv:
c.numberOfEmployees > 50

context c : Company inv enoughEmployees:
c.numberOfEmployees > 50

Pre- and Postconditions

- The OCL expression can be part of a Precondition or Postcondition, corresponding to «precondition» and «postcondition» stereotypes of Constraint associated with an Operation or other behavioral feature.

context Typename::**operationName**(**param1** : Type1, ...):
ReturnType

pre : **param1** > 5

post: **result** = 55

- The name **self** can be used in the expression referring to the object on which the operation was called.
- The reserved word **result** denotes the result of the operation, if there is one.

Objects and Properties

- *OCLExpressions* can refer to Classifiers, e.g., types, classes, interfaces, associations (acting as types), and datatypes. Also all attributes, association-ends, methods, and operations without side-effects that are defined on these types, etc. can be used.
- OCL refers to attributes, association-ends, and side-effect-free methods/operations as being *properties*. A property is one of:
 - ***an Attribute***
 - ***an AssociationEnd***
 - ***an Operation with isQuery being true***

OCL (Object Constraint Language) – The Mortgage Example

How to express constraints?

Can we express the following info on the diagrams?

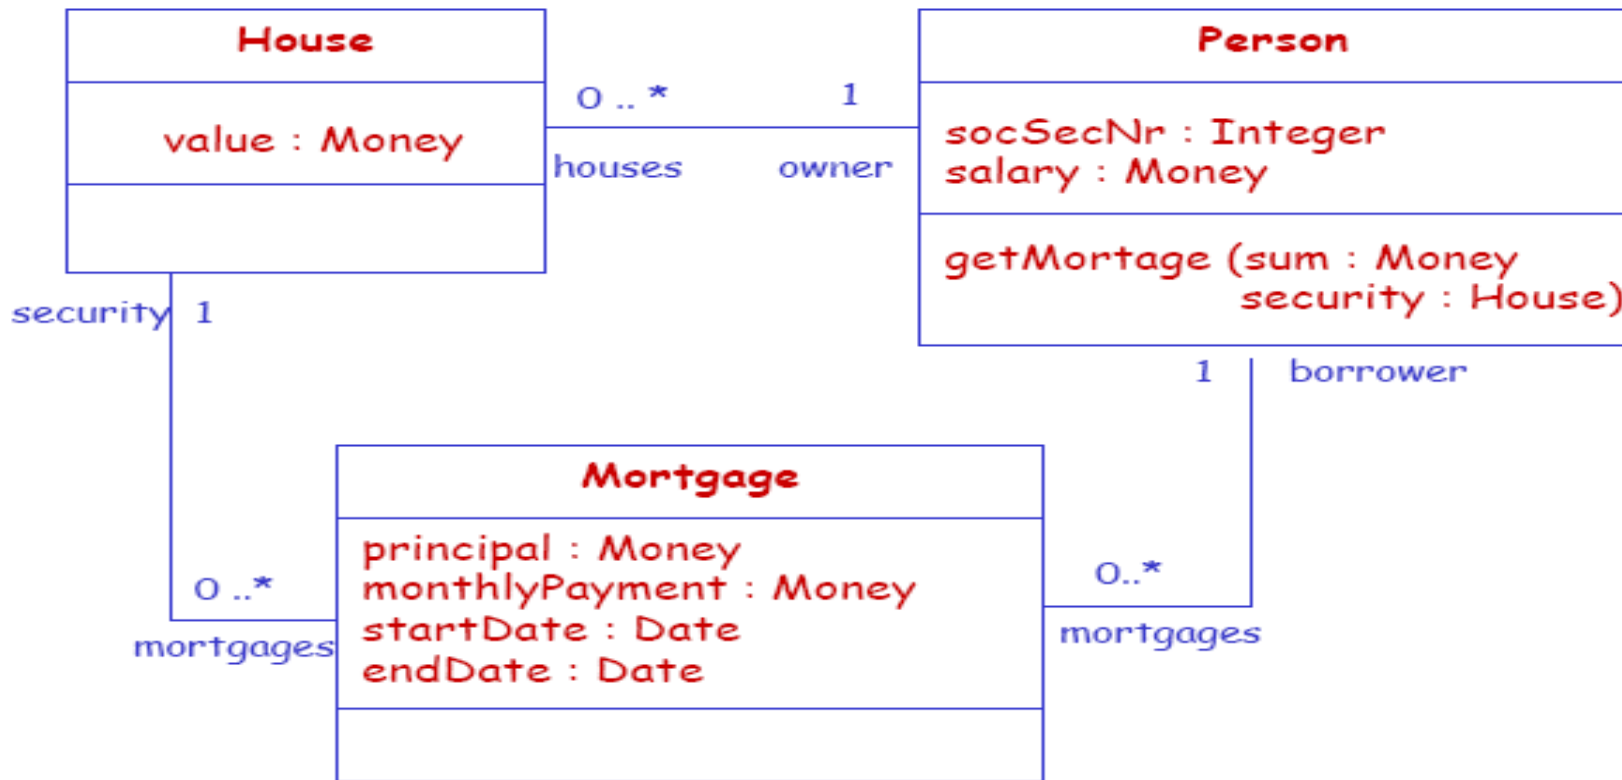

1. A person may have a mortgage on a house only if that house is owned by himself.
2. The start date for any mortgage must be before the end date.
3. The social security number of all persons must be unique.
4. A new mortgage will be allowed only when the person's income is sufficient.
5. A new mortgage will be allowed only when the counter value of the house is sufficient.

context Mortgage

inv: security.owner = borrower

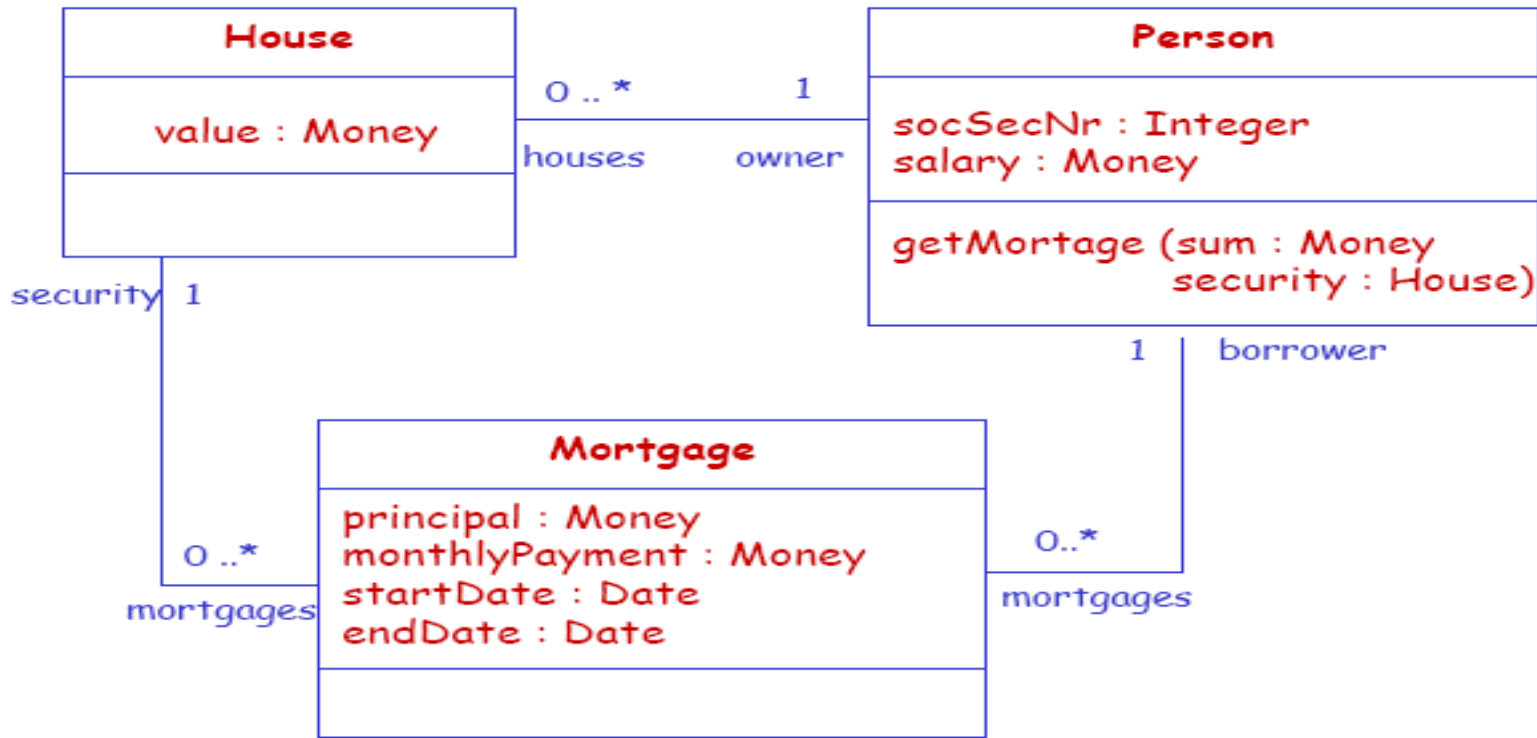

/ A person may have a mortgage on a house only if that house is owned by himself.*/*

context Mortgage

inv: startDate < endDate

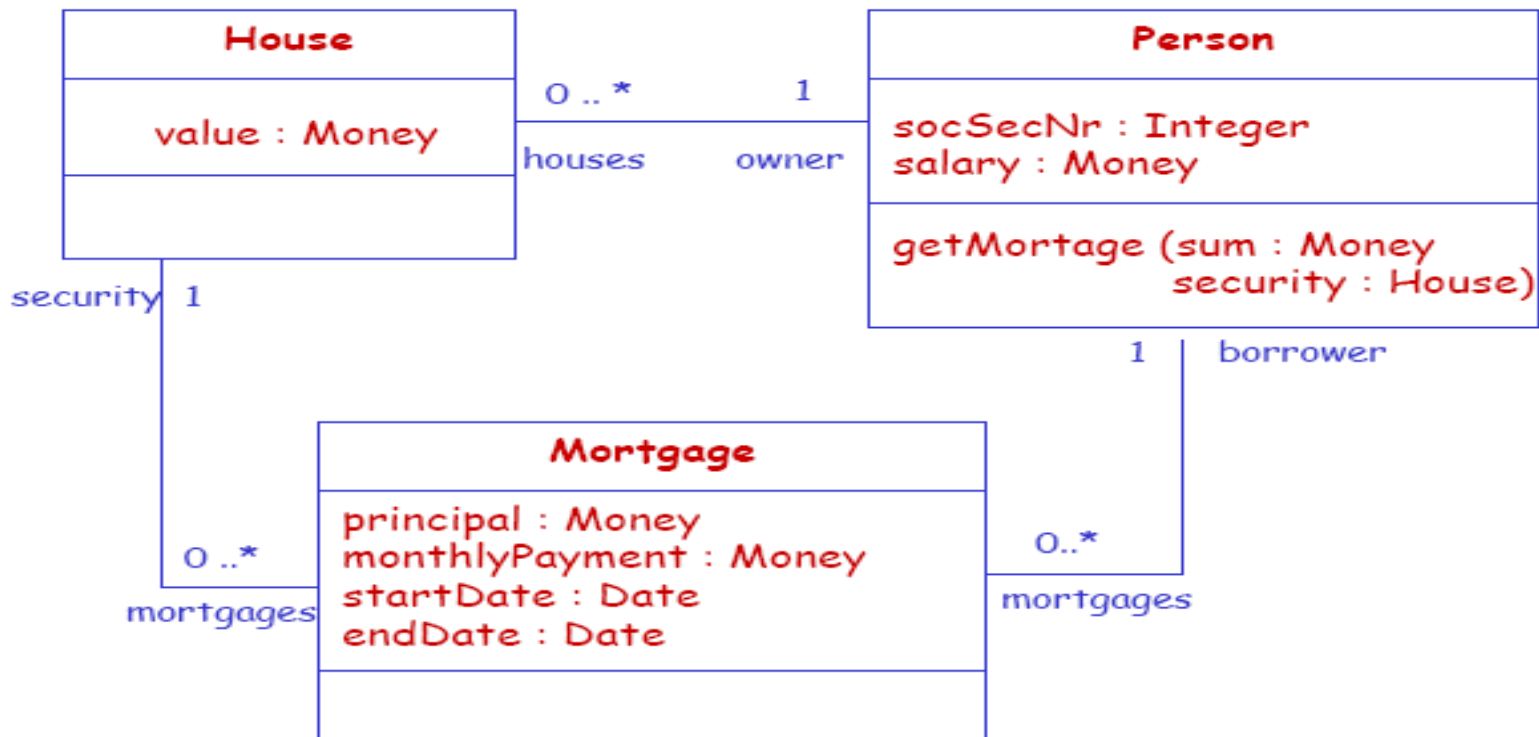

`/* The start date for any mortgage must be before the end date.*/`

context Person

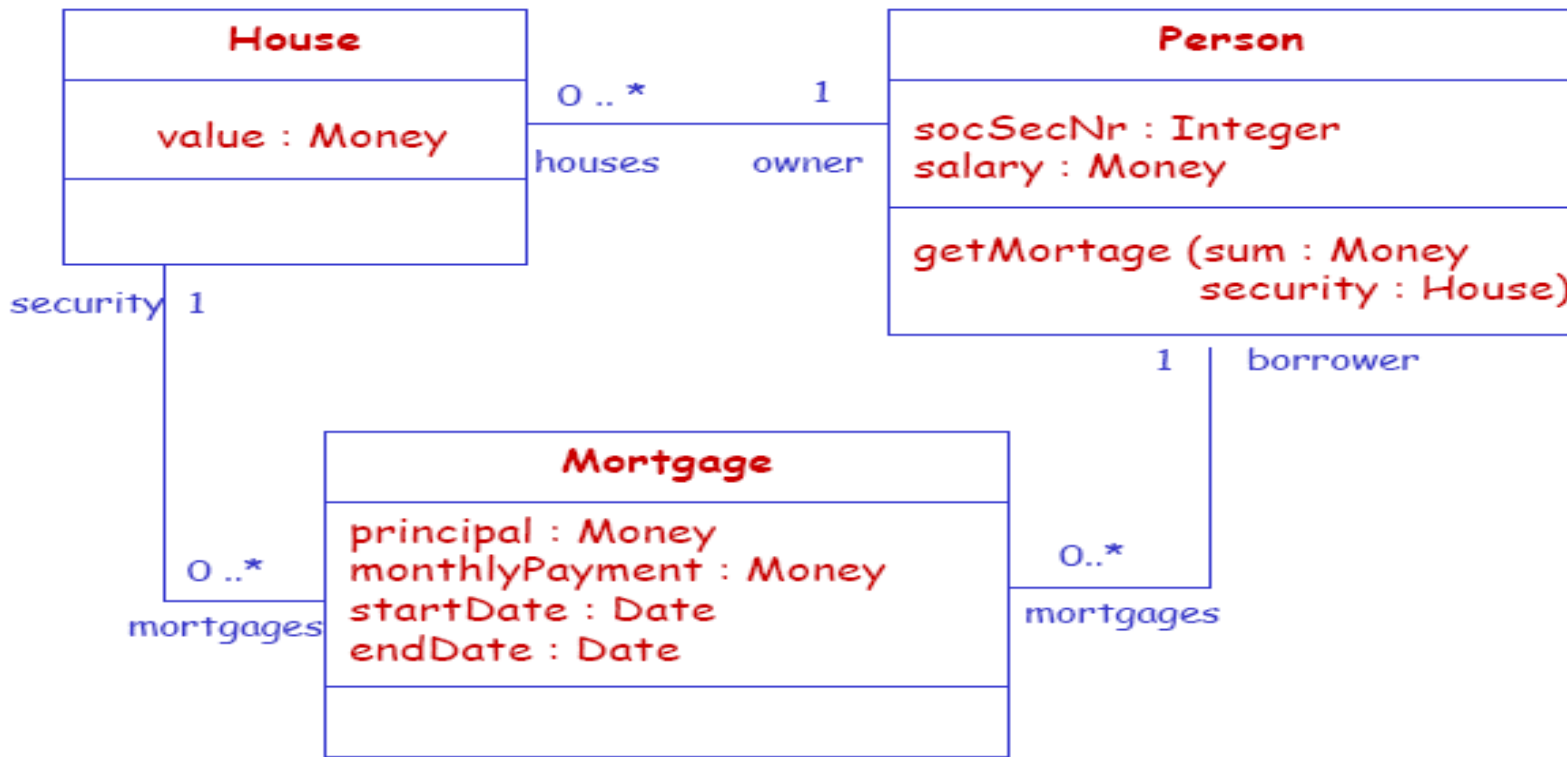

inv: Person::allInstances() -> isUnique (socSecNr)

/ The social security number of all persons must be unique.*/**

context Person::getMortgage(sum: Money, security: House)
Pre: self.mortgages.monthlyPayment -> sum() <= self.salary * 0.30

/ A new mortgage will be allowed only when the person's income is sufficient.*/*

context Person::getMortgage(sum: Money, security: House)

Pre: security.value >= self.mortgages.principal->sum()

/ A new mortgage will be allowed only when the counter value of the house is sufficient.*/*

Constraints Usage

- ❑ Avoid any potential misunderstandings
 - ❑ Not everyone is aware of these constraints
 - ❑ People may make different assumptions.
- ❑ Enable automatic model analysis/transform.
 - ❑ Computer has no “intuition”.
 - ❑ Software tools are possible only if the model contains complete information.
- ❑ Document your design decisions.

Characteristics of OCL 1/2

- ✓ OCL is a constraint and query language
 - ✓ A constraint is a restriction on one or more values of a model.
 - ✓ OCL can be used to write not only constraints, but any query expression.
 - ✓ It is proved that OCL has the same capability as SQL.
- ✓ OCL has a formal foundation, but maintain the ease of use.
 - ✓ The result is a precise language that should be easily read and written by average developers.

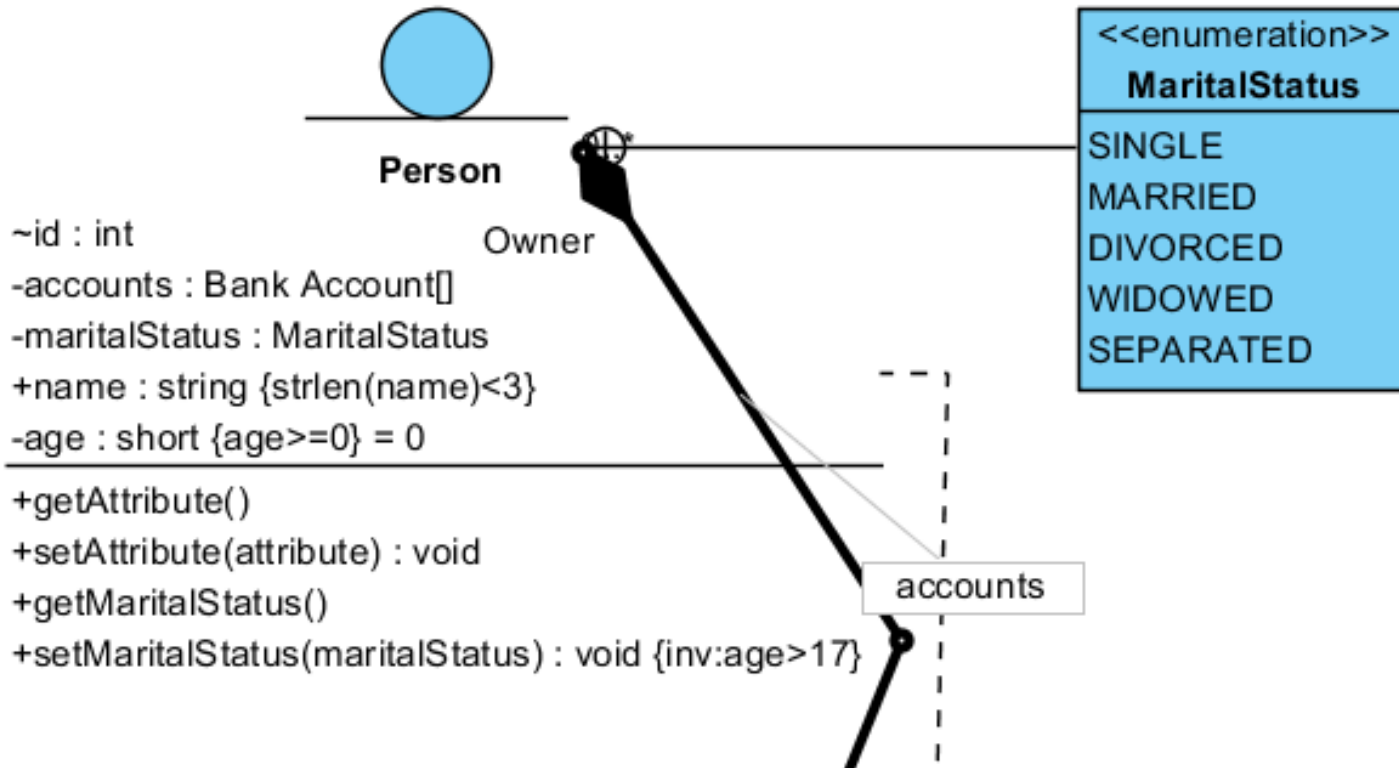

Characteristics of OCL 2/2

- ✓ OCL is strongly-typed
 - ✓ This allows OCL expressions can be checked during modeling, before execution.
 - ✓ What is the benefit?
- ✓ OCL is a declarative language
 - ✓ OCL expressions state what should be done, but not how.

Timing Diagrams (UML 2.0)

Source for these slides:

Learning UML 2.0,
by Kim Hamilton, Russell Miles

.....
Publisher: **O'Reilly**
Pub. Date: **April 2006**

✓ **Interaction diagrams:**

- ✓ sequence diagrams focus on message order
- ✓ communication diagrams show the links between participants
- ✓ *But: we need interaction diagrams to model detailed timing information!*

✓ **In timing diagrams:**

- ✓ each event has timing information associated with it

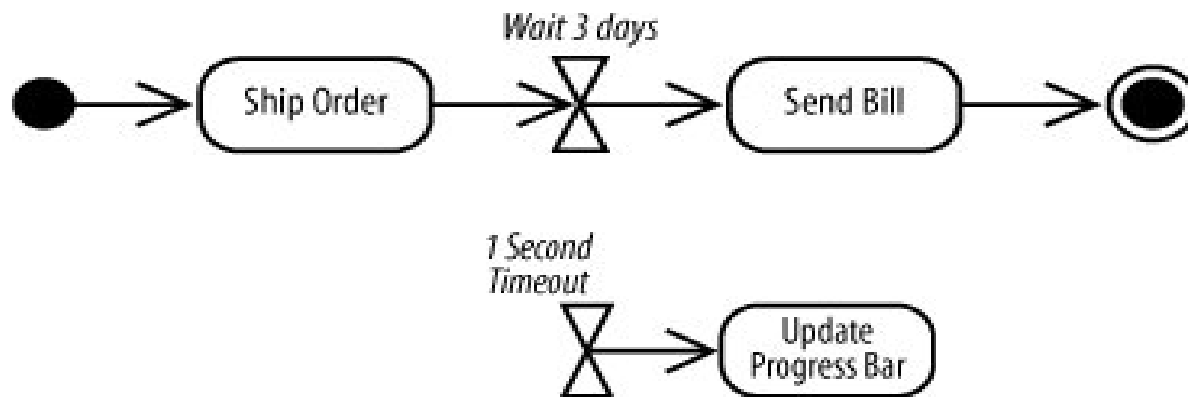

Event Timing Information:

- Describes:
 - when the event is invoked,
 - how long it takes for another participant to receive the event, and
 - how long the receiving participant is expected to be in a particular state.
- Event timing could be expressed within activity diagrams (UML 2.x).

Time Events (slide from previous lesson)

- A time event with no incoming flows models a repeating time event

Need of Timing Diagrams

- Although sequence diagrams and communication diagrams are very similar,
- timing diagrams add completely new information
- that is not easily expressed on any other form of UML interaction diagram.

Introducing timing: oscilloscope views

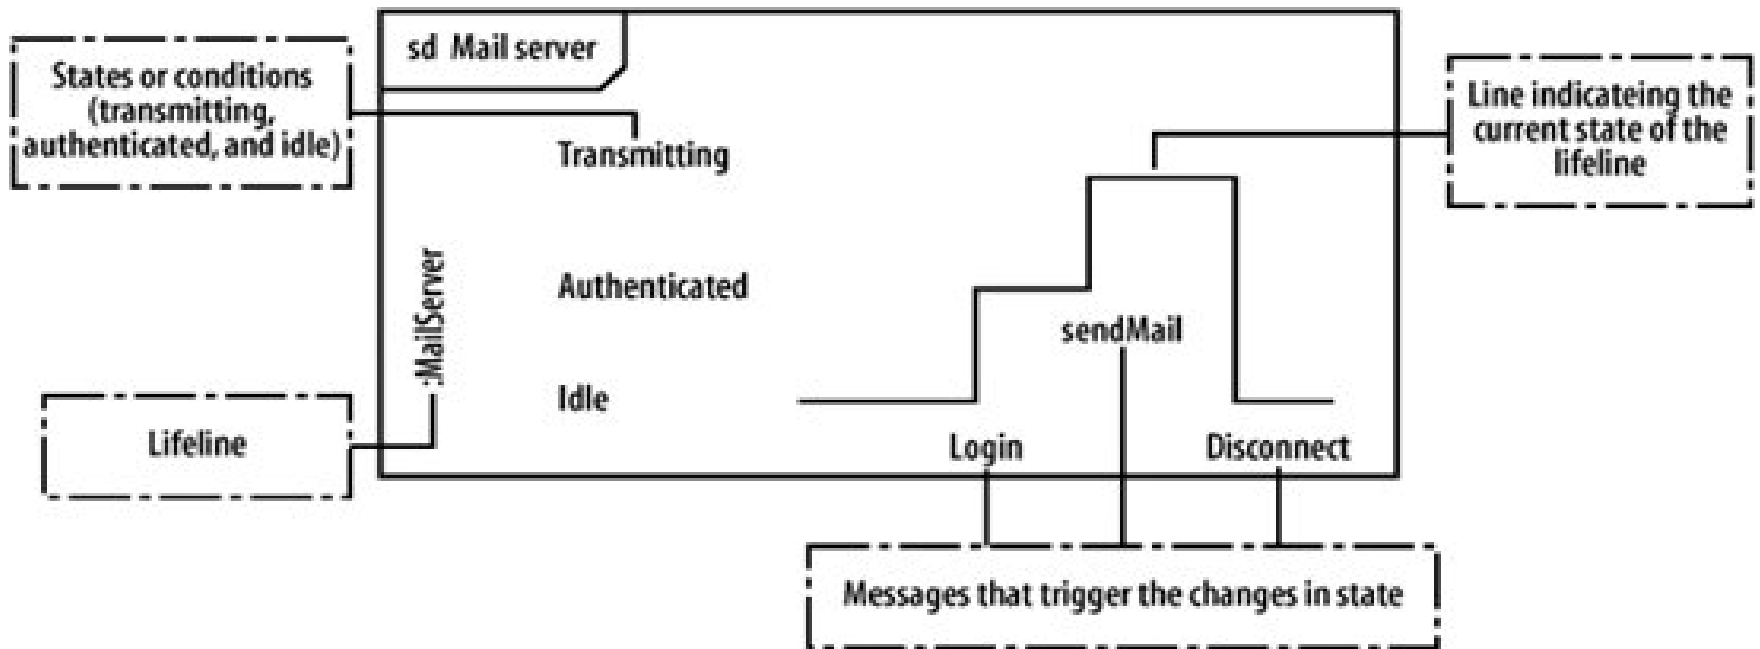

A logic analyzer captures a sequence of events as they occur on an electronic circuit board

Events and states on timing diagrams

- On a timing diagram:
 - events are the logic analyzer's signals, and
 - states are the states that a participant is placed in

Sample timing diagram for a mail server

From use case and requirements...

Sample use case: Create a new Regular Blog Account

Requirement A.2

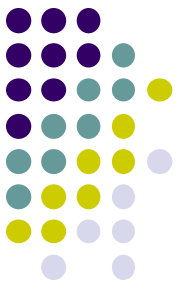

- The content management system shall allow an administrator to create a new regular blog account, provided the personal details of the author are verified using the Author Credentials Database.

...To sequence diagrams – sequential ordering...

Create a new Regular Blog Account interaction

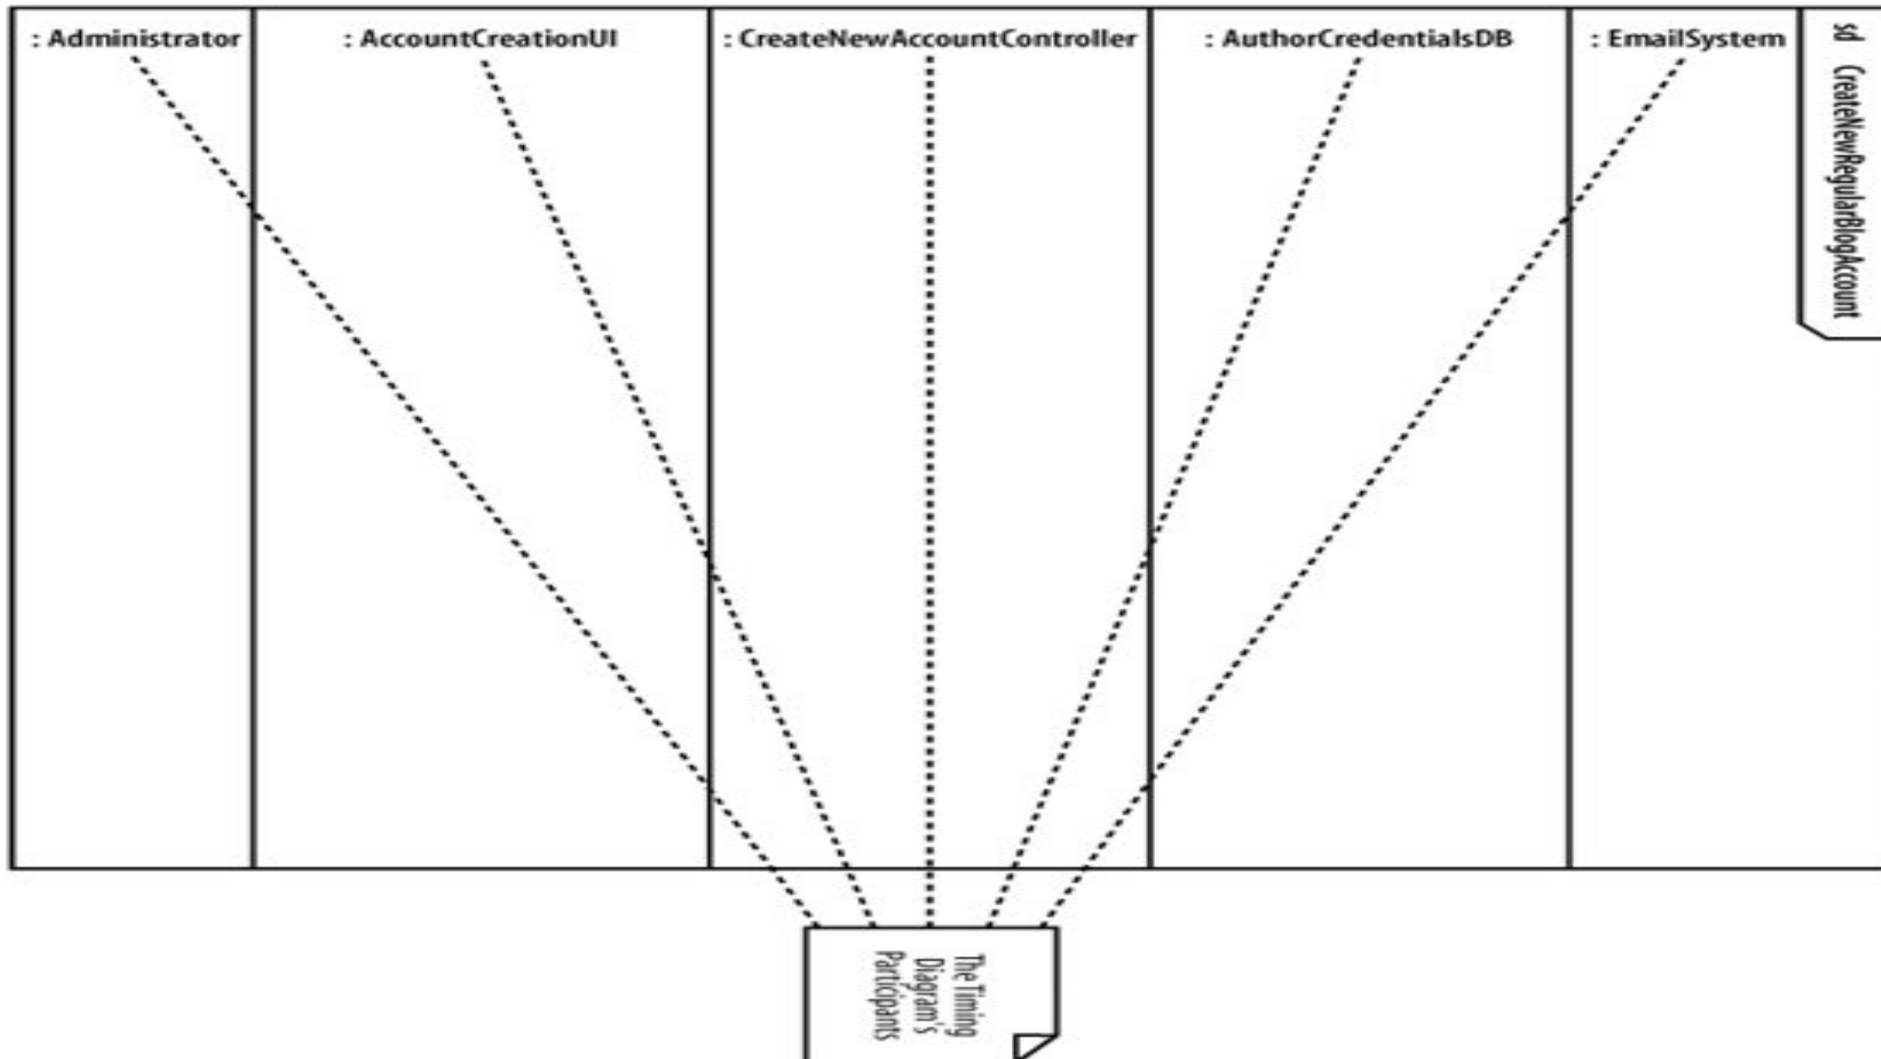

...Through Adding Timing Constraints in System Requirements...

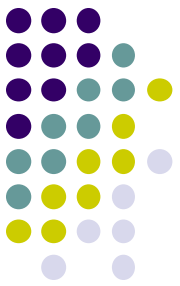

Requirement A.2 (Updated)

- The content management system shall allow an administrator to create a new regular blog account within five seconds of the information being entered,
- provided the personal details of the author are verified using the Author Credentials Database.

...To a Timing Diagram – first define the Participants

Next – add States

States are written horizontally on a timing diagram and next to the *participant* that they are associated with

Exact Time Measurements and Relative Time Indicators

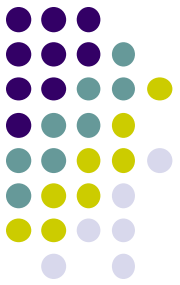

- Time measurements are placed on a timing diagram as a ruler along the bottom of the page

- Relative time indicators are particularly useful when you have timing considerations such as "ParticipantA will be in State1 for half of the time that ParticipantB is in State2"

The Participant's State-Line

1/2

The Participant's State-Line 2/2

- Create a new Regular Blog Account timing diagram - updated to show the state of each participant at a given time during the interaction.
- p1:Participant's state-line indicates that it is in State1 for 1 unit of time, State2 for three units of time, and State3 for roughly five units of time (before returning to State1 at the end of the interaction)
- In practice, you would probably add both events and states to a timing diagram at the same time.

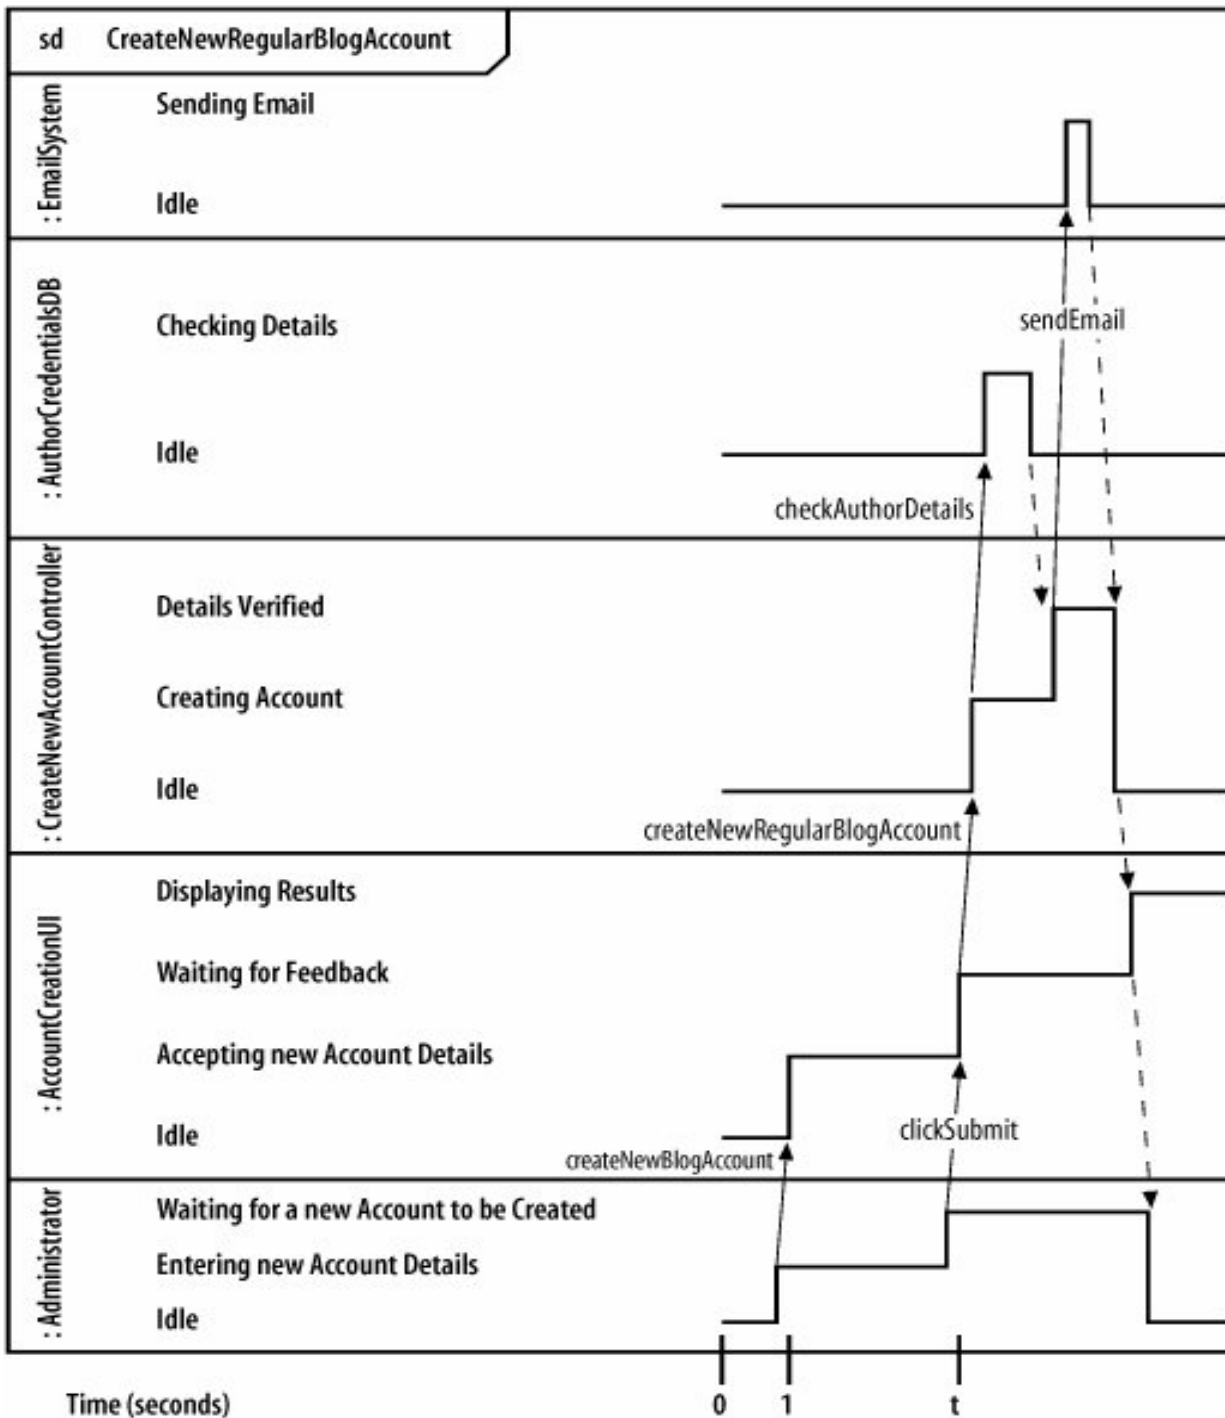

Create a new Regular Blog Account timing diagram

(the single t value below represents a single second wherever it is mentioned on any further timing constraints on the diagram)

Adding events and messages

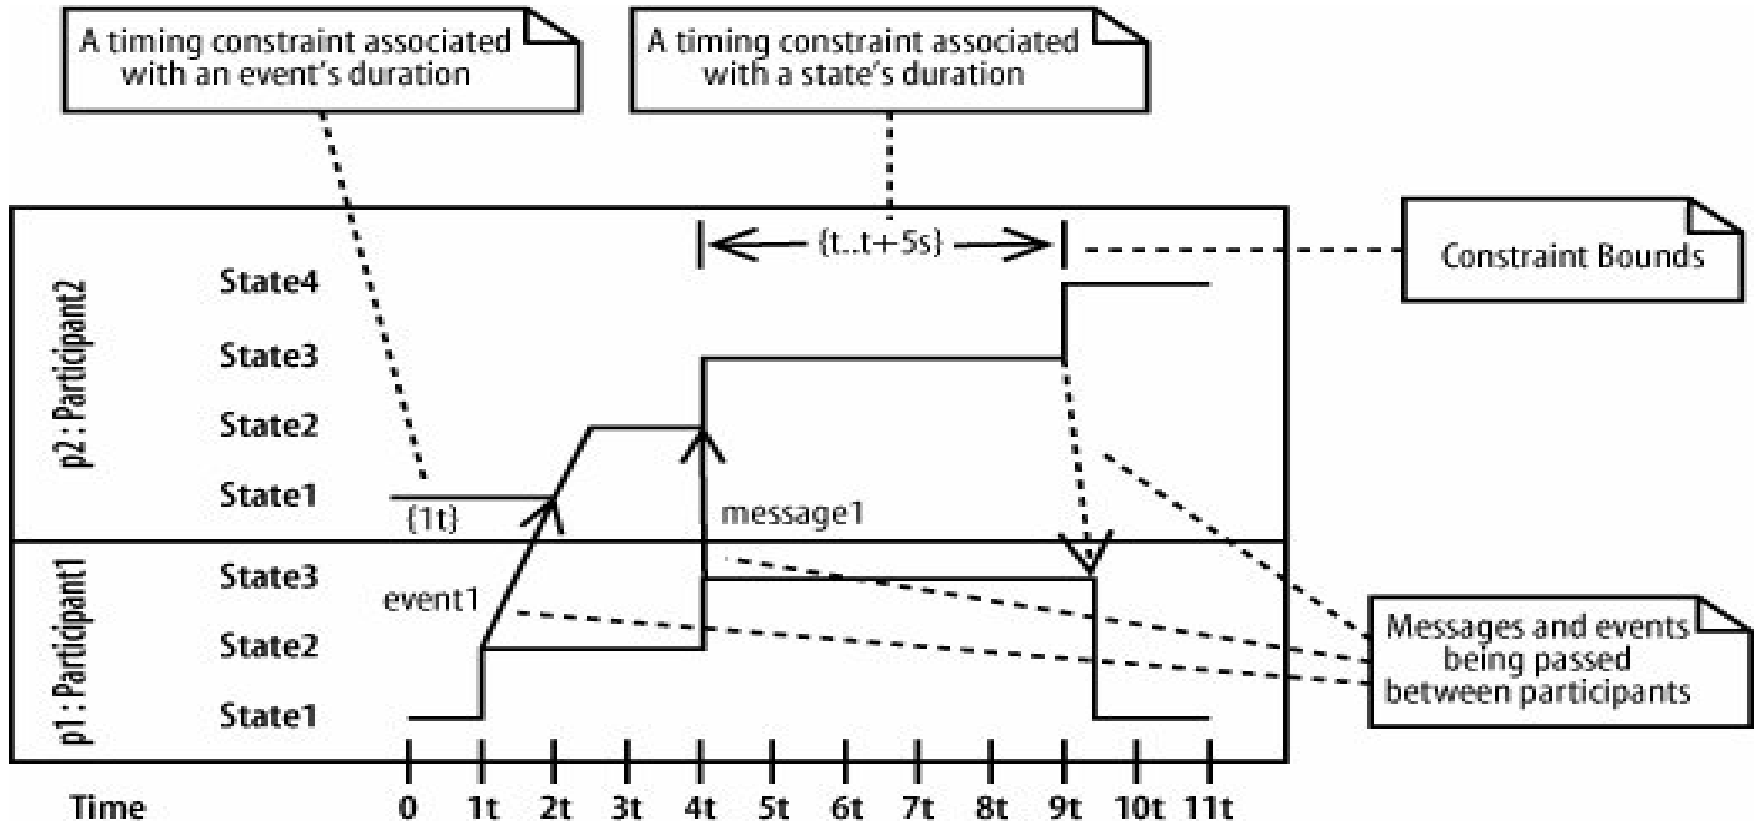

Events on a timing diagram can even have their own durations, as shown by event1 taking 1 unit of time from invocation by p1:Participant1 and reception by p2:Participant2

**Participant
state
changes
make much
more sense
when you
can see the
events that
cause them**

Timing Constraints

Timing constraints can be associated with an event or a state and may or may not be accompanied by constraint boundary arrows

Timing Constraints Format

Timing Constraint

Description

{t..t+5s}	The duration of the event or state should be 5 seconds or less.
{<5s}	The duration of the event or state should be less than 5 seconds. This is a slightly less formal than {t..t+5s}.
{>5s, <10s}	The duration of the event or state should be greater than 5 seconds, but less than 10 seconds.
{t}	The duration of the event or state should be equal to the value of t. This is a relative measure, where t could be any value of time.
{t..t*5}	The duration of the event or state should be the value of t multiplied 5 times. This is another relative measure (t could be any value of time).

From when the :Administrator clicks on submit until the point at which the system has created a new account, no more than five seconds have passed

The regular Timing Diagram notation : good when *fewer states* need to be shown.

The alternative Timing Diagram Notation : good when *many states* need to be shown.

• The regular timing diagram notation (over) does not scale well when you have many participants that can be put in many different states during an interaction's lifetime.

• If a participant is placed in many different states during the course of the interaction, then it is worth considering using the alternative notation (below).

Note:
the alternate notation is more compact and manageable in a situation where there are many states per participant

Conclusions

- Interaction timing is most commonly associated with real-time or embedded systems, but it certainly is not limited to these domains.
- In a timing diagram, each event has timing information associated with it that accurately describes:
 1. **when the event is invoked,**
 2. **how long it takes for another participant to receive the event, and**
 3. **how long the receiving participant is expected to be in a particular state.**
- Although sequence diagrams and communication diagrams are very similar, timing diagrams add completely new information that is not easily expressed on any other form of UML interaction diagram.
